What are benzodiazepines?

Benzodiazepines (pronounced ‘ben-zoh-die-AZ-a-peens’) are depressant drugs. This means that they slow down the activity of the central nervous system and the messages travelling between the brain and the body. They do not necessarily make a person feel depressed. Other depressants include alcohol, cannabis and heroin.

Benzodiazepines, also known as minor tranquillisers, are most commonly prescribed by doctors to relieve stress and anxiety and to help people sleep. They can also be used to treat alcohol withdrawal and epilepsy. However, there is increasing concern among medical professionals about the risks of using these drugs, particularly when they are used for a long time.

Benzodiazepines can cause overdose, particularly when used with alcohol or other drugs. They are also associated with dependence and withdrawal symptoms, even after a short period of use. As a result, benzodiazepines are not suggested as the first option for pharmacological treatment of insomnia, anxiety or other health concerns.

Some people use benzodiazepines illegally to get high or to help with the ‘come down’ effects of stimulants such as amphetamines or cocaine.

Slang names

Benzos, tranx, sleepers, downers, pills, xannies, serras (Serepax®), moggies (Mogadon®), normies (Normison®).

Other types of commonly used depressants

- Alcohol
- GHB
- Kava

Types of benzodiazepines

There are three types of benzodiazepines: long, intermediate and short acting. Short-acting benzodiazepines have stronger withdrawal or ‘come down’ effects and can be more addictive than long-acting ones.2

Benzodiazepines are known by their chemical (generic) name or their brand name. In each case the drug is exactly the same – it’s just made by a different company. Some common benzodiazepines are:

### Pharmaceutical names

<td>Euhypnos®, Normison®</td>
<td>Short-acting</td>
</tr>
<tr>
<td>alprazolam</td>
<td>Xanax®, Kalma®, Alprax®</td>
<td>Short-acting</td>
</tr>
</tbody>
</table>

How are they used?

Benzodiazepines are usually swallowed. Some people also inject them.

Effects of benzodiazepines

**There is no safe level of drug use.** Use of any drug always carries some risk. It’s important to be careful when taking any type of drug.

Benzodiazepines affect everyone differently, but the effects may include:

- depression
- confusion
- feelings of isolation or euphoria
- impaired thinking and memory loss
- headache
- drowsiness, sleepiness and fatigue
- dry mouth
- slurred speech or stuttering
- double or blurred vision
- impaired coordination, dizziness and tremors
- nausea and loss of appetite
- diarrhoea or constipation. ³

Injecting benzodiazepines may also cause:

- vein damage and scarring
- infection, including hepatitis B, hepatitis C, HIV and AIDS
- deep vein thrombosis and clots causing loss of limbs, damage to organs, stroke and possibly death.

Injecting drugs repeatedly and sharing injecting equipment with other people increases the risk of experiencing these effects. ⁴

Benzodiazepines are not generally recommended for use during pregnancy or breastfeeding, as they are associated with pre-term delivery, low birth weight and potential birth defects. ⁵, ⁶ They may also be dangerous for people with acute asthma, emphysema or sleep apnoea; advanced liver or kidney disease; or people with a history of substance use disorders, as it can lead to dependence. ⁷, ⁸ Benzodiazepines should be prescribed with caution for elderly people, as it can increase the risk of falls and injury. ⁹
Overdose

Benzodiazepines are often present in patients who have intentionally or accidentally overdosed. If you take a large amount, you could overdose. Call an ambulance straight away by dialling triple zero (000) if you have any of the symptoms below (ambulance officers don’t need to involve the police):

• over-sedation or sleep
• jitteriness and excitability
• mood swings and aggression
• slow, shallow breathing
• unconsciousness or coma
• death (more likely when taken with another drug such as alcohol).3

Long-term effects

• Regular use of benzodiazepines may cause:3, 11
  • impaired thinking or memory loss
  • anxiety and depression
  • irritability, paranoia and aggression
  • personality change
  • weakness, lethargy and lack of motivation
  • drowsiness, sleepiness and fatigue
  • difficulty sleeping or disturbing dreams
  • headaches
  • nausea
  • skin rashes and weight gain
  • addiction
  • withdrawal symptoms (see below).3

There is some evidence that long-term, heavy use of benzodiazepines is a risk factor for epilepsy, stroke and brain tumours.32

Using benzodiazepines with other drugs

The effects of taking benzodiazepines with other drugs can be unpredictable and dangerous, and could cause:

• **Benzodiazepines + alcohol or opiates (such as heroin):** breathing difficulties, an increased risk of overdose and death.
• **Benzodiazepines + some pharmaceutical drugs:** strong pain-relievers, antidepressants, anticonvulsants, anti-psychotics, some anti-histamines and over the counter medications can have an adverse effect when taken with benzodiazepines and lead to breathing difficulties, an increased risk of overdose and death.8

The use of benzodiazepines to help with the come down effects of stimulant drugs (such as amphetamines or ecstasy) may result in a cycle of dependence on both types of drug.

Withdrawal

Giving up benzodiazepines after using them for a long time is challenging because the body has to get used to functioning without them. This is why it’s important to seek advice from a health professional when planning to stop taking benzodiazepines. Do not stop taking benzodiazepines suddenly, as sudden withdrawal can cause seizures.3

Withdrawal symptoms vary from person to person and are different depending on the type of benzodiazepine being taken. Symptoms can last from a few weeks to a year and can include:

• headaches
• aching or twitching muscles
• dizziness and tremors
• nausea, vomiting, stomach pains
• bizarre dreams, difficulty sleeping, fatigue
• poor concentration
• anxiety and irritability
• altered perception, heightening of senses
• delusions, hallucinations and paranoia
• seizures.3

Getting help

If your use of benzodiazepines is affecting your health, family, relationships, work, school, financial or other life situations, you can find help and support.

Always call an ambulance on triple zero (000) if an overdose is suspected: tell the paramedic exactly what has been taken. Paramedics are there to help and will not involve the police unless there is a danger to themselves or others.
